ABSTRACT OF
MASTER'S THESIS

Author: Eetu Kupiainen

Title:
What metrics are agile industrial teams using, why and how? A systematic literature review

Date:	Fix me June 18, 2011	**Pages:**	47
Major:	Software Engineering	**Code:**	T3003
Supervisor:	Prof. Casper Lassenius		
Instructors:	Juha Itkonen D.Sc. (Tech.) Mika Mäntylä D.Sc. (Tech.)		

Agile development methods are increasing in popularity, yet there are limited studies on the reasons and use of metrics in industrial agile development.

This paper presents results from a systematic literature review. Based on the study, metrics and their use are focused to the following areas: **??**, **??**, **??**, **??**, **??**, **??** and **??**. The findings are mapped against agile principles and it seems that the use of metrics supports the principles with some deviations.

Surprisingly, we find little evidence of the use of code metrics. Also, we note that there is a lot of evidence on the use of planning and tracking metrics. Finally, the use of metrics to motivate and enforce process improvements as well as applicable quality metrics can be interesting future research topics.

Keywords: agile, metrics, measurement, systematic literature review

DIPLOMITYÖN TIIVISTELMÄ

Tekijä:	Eetu Kupiainen		
Työn nimi:	Mitä mittareita ketterät tiimit teollisuudessa käyttävät, miksi ja miten? Systemaattinen kirjallisuuskatsaus		
Päiväys:	Fix me 18. kesäkuuta 2011	**Sivumäärä:**	47
Pääaine:	Ohjelmistotuotanto ja liiketoiminta	**Koodi:**	T3003
Valvoja:	Prof. Casper Lassenius		
Ohjaajat:	Tkt Juha Itkonen Tkt Mika Mäntylä		

Noh, mistäs teit dippas?

- Nooh, tutkin minkälaisia mittareita ketterät tiimit teollisuudessa käytti, miten ja miksi.

Okei, no mikäs on sen dipan tärkein anti?

- Noh, kategorisoin mittareiden käyttöä ja syitä, johon halukkaat voivat tarkemmin tutustua.

No miksi kukaan haluis noita ihmetellä?

- Mulla (timolla) on sellainen teoria, että on syitä, jotka aiheuttaa ohjelmistoprojektien epäonnistumisia. Mäppäsin löydettyjä mittareita em. syykategorioita vasten, joten voin sanoa että mitä mittareita kannattaisi käyttää jos haluaa ehkäistä tietyistä syistä johtuvia failureita.

- Lisäksi mä näytän miten suurempi osa on reaktiivisia mittareita.

- Lisäksi ideana oli, että pystyisin luomaan jonkinlaisen tärkeiden mittareiden luokittelun... Tämä on osoittautunut aika hankalaksi. Mulla on nyt yksittäisiä mittareita, joita on ylistetty - ja osaan myös sanottu miksi. Ne voin esittää. Lisäksi jos kvantitatiivisesti ajateltuna, näyttää siltä että effort estimaatit on tärkeitä agiilissa, koska niitä näkyi paljon. Toisinpäin ajateltuna, eli mitkä ei oo tärkeitä, niin vois sanoa et koodimittarit. Niitä ei ollut juuri yhtään.

Asiasanat:	ketterä, mittarit, mittaus, systemaattinen kirjallisuuskatsaus

Chapter 1

Introduction

Software metrics have been studied for decades and several literature reviews have been published. Yet, the literature reviews have been written from an academic viewpoint that typically focuses on the effectiveness of a single metric. For example, Catal et al. review fault prediction metrics (Catal and Diri, 2009), Purao and Vaishnavi (2003) review metrics for object oriented systems and Kitchenham (2010) performs a mapping of most cited software metrics papers. According to the researcher's knowledge there are no systematic literature reviews on the actual use of software metrics in the industry.

Agile software development is becoming increasingly popular in the software industry. The agile approach seems to be contradicting with the traditional metrics approaches. For example, the agile emphasizes working software over measuring progress in terms of intermediate products or documentation, and embracing the change invalidates the traditional approach of tracking progress against pre-made plan. However, at the same time agile software development highlights some measures that should be used, e.g., burndown graphs and 100% automated unit testing coverage. However, measurement research in the context of agile methods remains scarce.

The goal of this paper is to review the literature of actual use of software metrics in the context of agile software development. This study will lay out the current state of metrics usage in industrial agile software development based on literature. Moreover, the study uncovers the reasons for metric usage as well as highlights actions that the use of metrics can trigger.

This study covers the following research questions:

- RQ1: Why are metrics used?
- RQ2: What actions do the use of metrics trigger?
- RQ3: Which metrics are used?

- RQ4: What metrics are important?

1.1 Structure of the Thesis

This thesis is structured as follows. Chapter 3 describes how the SR was conducted. Chapter 4 reports the results from the study. Chapter 5 discusses about the findings and how they map to agile principles. Chapter 6 concludes the paper. !Fixme **Final structure** Fixme!

Chapter 2

Background

2.1 Agile software development

Agile development methods have emerged to the software world ruled by traditional heavyweight methods. In agile methods the focus is in lightweight working practices, constant deliveries and customer collaboration over long planning periods, heavy documentation and inflexible development phases.

Agile manifesto created by agile enthusiasts (Beck et al., 2007) lists agile principles that give an idea what is agile development about. Popular agile development methods include Scrum (Schwaber and Beedle, 2002), Extreme Programming (Beck and Andres, 2004) and Kanban (Anderson, 2010).

2.2 Related work

Hartmann and Dymond (2006) don't provide any specific agile metrics but rather describes how agile metrics should be chosen and how they should be introduced to the organization. Also, they provide a set of heuristics for agile metrics.

!Fixme **tää jäi vähän laihaks** Fixme!

2.3 Systematic literature review

Systematic literature review is a research method originated from the field of medicine !Fixme **viite** Fixme!. The overarching idea is to aggregate and synthetisize existing knowledge regarding a research topic. This rigorous and audible evaluation method can facilitate theory development and point out gaps in research (Webster and Watson, 2002).

2.4 Causes for software project failures

2.5 Evidence based software engineering

2.6 Previous metric research

Chapter 3

Review method

Systematic review (SR) was chosen as research method because the study is more about trying to understand a problem instead of trying to find a solution to it. Also, there was already existing literature that could be synthesized.

3.1 Protocol development

Kitchenham's guide for SRs (Kitchenham, 2004) was used as a basis for developing the review protocol. Additionally, a SR on agile development (Dybå and Dingsøyr, 2008) and a SR on SR (Kitchenham and Brereton, 2013) were used to further understand the challenges and opportunities of SRs. The protocol was also iterated in weekly meetings with the instructors, as well as in a pilot study.

3.2 Search and selection process

The strategy for finding primary studies was following:

- Stage 1: Automated search
- Stage 2: Selection based on title and abstract
- Stage 3: Selection based on full text. Conduct data extraction and quality assessment.

Table 3.1 shows the selection funnel in terms of the number of papers after each stage.

Table 3.1: Paper selection funnel

Stage	Amount of papers
Stage 1	774
Stage 2	163
Stage 3	29

Scopus database [1] was used to find the primary documents with automated search. Keywords include popular agile development methods and synonyms for the word metric. The search was improved incrementally in three phases because some key papers and XP conferences were not found initially. The search strings, hits and dates can be found from appendix A.

The selection of the primary documents was based on inclusion criteria: *papers that present empirical findings on the industrial use and experiences of metrics in agile context.* The papers were excluded based on multiple criteria, mainly due to not conforming to requirements regarding empirical findings and agile and industrial context. Full criteria are listed in appendix B.

In stage 1, Scopus was used as the only search engine as it contained the most relevant databases IEEE and ACM. Also, it was able to find Agile and XP conference papers. Only XP Conference 2013 was searched manually because it couldn't be found through Scopus.

In stage 2, papers were included and excluded by the researcher based on their title and abstract. As the quality of abstracts can be poor in computer science (Kitchenham, 2004), full texts were also skimmed through in case of unclear abstracts. Unclear cases were discussed with the instructors in weekly meetings and an exclusion rule was documented if necessary.

The validity of the selection process was analysed by performing the selection for a random sample of 26 papers also by the second instructor. The level of agreement was 'substantial' with Kappa 0.67 (Landis and Koch, 1977).

Stage 3 included multiple activities in one work flow. Selection by full text was done, data was coded and quality assessment was done. Once again, if there were unclear papers, they were discussed in meetings. Also, selection of 7 papers was conducted by the second instructor with an 'almost perfect' agreement, Kappa 1.0 (Landis and Koch, 1977).

3.3 Data extraction

Integrated coding was selected for data extraction strategy (Cruzes and Dyba, 2011). It provided focus to research questions but flexibility regarding findings. Deductive coding would have been too restraining and inductive coding might have caused too much bias. Integrated coding made it possible to create a sample list of code categories:

- Why is measurement used?
- How is measurement used?
- Metric
- Importance related to metric
- Context

The coding started with the researcher reading the full text and marking interesting quotes with a temporary code. After, reading the full text the researcher checked each quote and coded again with an appropriate code based on the built understanding. In weekly meetings with the instructors, a rule set for collecting metrics was slowly built:

- Collect metric if team or company uses it.
- Collect metric only if something is said about why it is used, what actions it causes or if it is described as important.
- Don't collect metrics that are only used for the comparison and selection of development methods.
- Don't collect metrics that are primarily used to compare teams.

Atlas.ti Visual QDA (Qualitative Data Analysis), version 7.1.x was used to collect and synthesize the qualitative data. Amount of found quotes per code can be seen in Section 3.3.

To evaluate the repeatability of finding the same metrics, second instructor coded metrics from three papers. Capture-recapture method (Seber, 2002) was then used which showed that 90% of metrics were found.

A quality assessment form adopted from (Dybå and Dingsøyr, 2008) was used to evaluate the quality of each primary study. Detailed list of quality assessment questions can be found in appendix C. Additionally, a relevancy factor was added to the same assessment to describe how useful the paper was for this study. The scale for the relevancy factor is:

Table 3.2: Amount of found quotes

Code	Amount of quotations
Why use this metric?	151
How is measurement used?	61
Metrics	108
Importance related to metric	45
Context	158

- 0 = doesn't contain any information regarding metrics and should be already excluded
- 1 = only descriptions of metrics with no additional info
- 2 = some useful information related to metrics
- 3 = a good amount of relevant information regarding metrics and metric usage

3.4 Data synthesis

Data synthesis followed the steps recommended by Cruzes and Dyba (2011). Process started by going through all quotes within one code and giving each quote a more descriptive code describing the quote in high level. Then the descriptive codes were organized in groups based on their similarity. These groups were then given high level codes which are seen as categories in **??**.

Chapter 4

Results

This chapter presents the results from the systematic literature review. Table 4.1 shows the distribution of primary studies by publication channels. Table 4.3 lists the distribution of agile methods and Table 4.4 lists the distribution of domains.

4.1 Overview of studies

4.1.1 Quality of studies

The perceived quality of the studies varied a lot (from 0 to 10). Even with many low quality studies they were included since they still provided valuable insight. For example in some cases experience reports can provide more valuable data than a high scoring research papers.

According to the assessment control group and reflexivity had lowest total scores while value for research, context and findings scored the highest.

4.2 Metrics & categorization

Metrics are listed by primary study in appendix, see Appendix D.

Found metrics are categorized using categorization by (Fenton and Pfleeger, 1998).

4.3 Why use metrics?

Dokumentoi rajatapaukset why vs how, ja selitä niitä. esim balance of flow

4.3.1 Identifying problems

Metrics were used to identify bottlenecks in the process. Cumulative number of work items over time metric was used to identify bottlenecks in the development process [S22]. Monitoring Work-in-progress (WIP) was used to spot blocked work items and also the development phase where the blockage occurred [S2]. Cost types, rate of requirements over phases and variance in handovers were for process improvement by spotting bottlenecks and uneven requirement flows [S21].

Metrics were able to identify waste, development phases were no value is added, in software processes. Value stream maps (VSM) were used to spot waste in the development process [S18]. Lead time was used to identify waste of waiting [S22]. Measuring story flow percentage allowed identification of waste related to context shifts [S13].

Metrics were used to identify problems. Defect trend indicator was used to provide the project manager an ISO/IEC 15939:2007 compatible indicator for problems with the defect backlog. Basically, the indicator showed if the defect backlog will increase, stay the same or decrease in the coming week [S25]. The project manager could then use the info to take necessary actions to avoid possible problems. Schedule performance index and cost performance index were used to monitor for deviances in the project's progress and providing early sign if something goes wrong [S16]. Developers at Avaya had issues with the 80/20 rule, where the last 20% of iteration takes the longest [S29]. With the metrics that their tool T3 provides (e.g Story percent complete) they were able to see the early symptoms of various problems that can cause delays, and react early.

Metrics were also used to find improvement opportunities. Number of work items per phase and lead time was used to spot instabilities in the process [S20]. If a measured value was outside the control limits it was defined an instability. This enabled process improvement. Monitoring schedule and costs with a dashboard allowed to spot for improvement opportunities at OCLC [S31].

Table 4.5: Quality assessment fo primary studies

Study	Research	Aim	Context	R.design	Sampling	Ctrl. Grp	Data coll.	Data anal	Reflexivity	Findings	Value	Total	Relevancy

Table 4.6: Add caption

Entities	Attributes	
Products	**Internal**	**External**
Product	Running tested features	Customer satisfaction x2, Net Promoter Score, numer of requests from customers, progress as working code
Test plan	Number of test cases	
Code	Technical debt in categories, technical debt in effort, violations of static code analysis	
Build	Build status x2, fix time of failed build	
Features	Remaining task effort, task's expected end date, task done, effort estimate x14, work in progress x3, number of days in maintenance, story complete percentage	Business value delivered, change requests per requirements
Requirements	Implemented vs wasted requirements, requirement's cost types, Percentage of stories prepared for sprint	
Defects		Defect trend indicator, predicted number of defects
Processes		
Testing	Defect count after testing, critical defects sent by customer, open defects x5, test success rate, test failure rate, faults per iteration, defects found in system test, defects deferred, test coverage, test growth ratio	Number of bounce backs, fault slips
Implementation	Velocity x13, number of unit tests x4, completed web pages, cost performance index, schedule performance index, planned velocity, common compo time, average velocity	Story flow percentage
Requirements engineering	velocity of elaborating features	
Whole development cycle	cycle time x2, lead time x4, processing time, queue time, maintenance effort, number of work items per phase x2, variance in handovers, rate of requirements per phase, throughput, queue, costs, schedule	
Resources		
Team	Check-ins per day x3, actual effort	Team effectiveness
Customer	Revenue per customer	

4.3.2 Planning

Prioritization was one of the main activities metrics were used for. Effort estimates were used to prioritize the features for next release and used as basis for resourcing [S9]. Teams use effort estimates to prioritize activities based on relative value and relative effort [S8]. At Verisign Managed Security Services, they used many attributes to prioritize their backlog and revenue per customer was described in more detail [S11]. At Timberline, they used Kano analysis as a 'voice of customer' so that prioritization decision could be based on facts instead of political power [S17]. Practitioners at Ericsson used cost types, rate of requirements over phases and variance in handovers for short term decisions related to requirements prioritization, staff allocation and planning decisions [S21].

Metrics were used to estimate how many and how large features could be taken under development. Velocity was used to improve effort estimates for next planning session, and that way it was easier to understand how large can the scope be for the next iteration [S16]. Leaders used estimates to check the if the planned scope would be possible to complete during the next iteration [S12]. At WMS, they used pseudo-velocity and average velocity to plan their releases [S23]. Lead time was used to understand if all planned corrections can be completed before release date [S24]. Story estimates were used to understand the iteration where different features will be completed [S29].

Other planning uses for metrics were resourcing decisions and development flexibility. At Timberline, they broke down requirements into smaller pieces that were estimated in effort to understand what skills are needed to complete the work [S17]. Marking tasks done and undone made it possible to take undone tasks for the next iteration [S12]. Developers would mark expected end date for task so the next one can plan their own work as effectively as possible thus reducing idle time. Stories and their effort estimates were used as the fundamental units of development for the iteration [S6]. Predicted number of defects was used to plan the removal of defects. If the removal of defects would not be well planned it could cause delays for the release and thus increase costs for the project [S25].

4.3.3 Progress tracking

4.3.3.1 Project progress

Metrics were used to monitor the progress of the project. Completed web pages was used as a measure of progress [S12]. Number of automated passing test steps was used as a measure of progress in terms of completed work [S5].

Breaking down tasks to 'kits' between 2 to 5 days enabled progress monitoring [S17]. Set of metrics(burndown, check-ins per day, number of automated passing test steps, number of new and open defects) was developed to manage risks and provide timely progress monitoring [S27]. Story percent complete metric was used to give assessment of progress [S29]. A team at NASA Ames Reserch center didn't want to spend resources on estimating features and instead focused on designing and developing their software solution. Every six weeks they demonstrated their progress to customer with working code [S30].

Other metrics were used to give higher level understanding of progress. Release burndown shows project trends and can be used to predict completion date [S16]. Release burndown also reflects addition or removal of stories. Cost types, rate of requirements over phases and variance in handovers were used to provide overview of progress [S21]. Metrics(burndown, check-ins per day, number of automated passing test steps) were used to communicate progress to upper management [S5] and ensure good progress to external observers and ensure that key risks were under control [S5,S27,S28].

4.3.3.2 Increase visibility

Metrics were used to make complexity easier to understand and more visible. Cost types, rate of requirements over phases and variance in handovers were used to increase the transparency of end-to-end flow in a complex system [S21]. Technical debt board was used to make technical debt issues visible and easier to manage [S4]. Metrics(burndown, check-ins per day, number of automated passing test steps, number of open and new defects) were used to replace individual perception with facts [S27].

Metrics were used to keep the team informed. Defect trend indicator was used to monitor defect backlog and spread the information to project members [S25]. Cycle time metrics were used to let the team track their own performance [S23]. Story percent complete metric were generated automatically when tests were run and thus kept everyone on the same page and eliminated schedule surprises. The metric results were required to be reported periodically as well [S29]. Release burndown made the correlation clear between work remaining and team's progress in reducing it [S16].

4.3.3.3 Accomplishing project goals

Metrics were used to get understanding how the project is going in terms of reaching goals. There was a need for simple indicator that would quickly tell if project is under control. Common compo time was used to understand if

project was in target for delivery [S17]. Monitoring WIP was used predict lead time which in turn will predict project schedule [S2]. Sprint burndown was used to tell the team if they were on track regarding the sprint commitments [S7]. Burndown was used to see if the team could meet their goals, and if not what could be done [S5]. Story flow percentage was used so that developer could finish a story in a steady flow [S13]. Burndown was used to mitigate the risk where developers spend too much time perfecting features over finishing all tasks of the iteration [S28].

4.3.3.4 Balance workflow

Metrics were used to balance workflow so that people working wouldn't feel overloaded. Inventory of requirements over time was used to identify large handovers of requirements that would cause overload situations. The aim was to have steady flow of requirements [S20]. Operations department was overloaded so they decided to start evaluating incoming work with Ops story points to level the workload [S8]. People should be respected by having balanced workload to avoid overload situations. Measuring number of requirements per phase would help noticing peaks [S22]. Timberline tried to pace work according to customer demand. However, too much work was pushed to development, which caused many problems, including developers feeling overworked. They started using common tempo time to make sure there would be balance of workflow [S17]. Component level burndown was used to decide on resource mobility [S5].

Metrics were used solve large handovers. Variance in handovers was used to guarantee that requirements would flow evenly [S21]. Mamdas was measuring check-ins per day metric, which measured how often code is committed to main trunk. The point was to avoid people from committing only at the end of the iteration and instead integrate early and often [S5]. At WMS Gaming, they had problems with large tasks blocking other work, so they set a rule that only certain size of tasks(8 story points) can be taken for development [S23].

4.3.4 Understand and improve quality

4.3.4.1 Understand level of quality

Metrics were used to understand the level of quality after the release. Net Promoter Score was measured because it was thought to be a pure measure of success, since it's measured from the customers [S7]. Number of change requests from customer was used as indicator customer satisfaction [S19].

Maintenance effort was used as an indicator of overall quality of the release product [S19]. Number of maintenance requests was used as an indicator of built in quality [S22].

Metrics were also used to understand the level of quality before the release. Faults per iteration were used to measure the product's quality [S5]. Defects found in system test was used to measure the quality of software delivered to system test process [S7]. Defects deferred was used to predict the quality customers would experience [S7].

4.3.4.2 Increase quality

Metrics were used to increase the level of quality. Governance mechanisms, which included a set of metrics (burndown, check-ins per day and number of automated passing test steps), were used to increase product quality [S28]. At T-Systems International, they used a set of metrics(build status, number of unit tests, test coverage, test growth ratio, violations of static code analysis) to improve project's internal software quality [S14]. Critical defects sent by customers were tracked and fixed to prevent losing customers [S3]. Build status was measured to prevent defects reaching production environment [S14]. Violations of static code analysis was used to prevent the existence of critical violations [S14]. Technical debt board was used to reduce technical debt [S4].

4.3.4.3 Ensure level of testing

Metrics were used to make sure product is tested enough. Test coverage was used to evaluate how well was the code tested [S14]. However, in Brown-field(legacy) projects it's better to measure test-growth-ratio since there might be not be that many tests in the existing code base. Work in progress was measured so it could be minimized. Otherwise there would be problems e.g when there would be lot of untested code [S17]. Using number of automated passing test steps dealt with decreasing the risk that the product would be un-thoroughly tested [S5]. Similarly, number of automated passing test steps was used to make sure regression tests are ran and passed every iteration [S5]. Story percent complete metric supports test driven development [S29].

4.4 What kind of effects did the use of metrics have?

4.4.1 Create improvement ideas

This sections describes improvement ideas that were created based on metrics.

When a waste of extra process(requirement would wait for long time before full specification) was identified in requirement specification with the help of lead time, processing time and queue time metrics, a solution idea was created where a quick high level proposal would be sent to customer without the need for in-depth specification [S18]. Customer could then use the high level proposal to evaluate if they want to pursue that requirement further. Similarly, two requirement specification phases could be combined when another waste of extra process was identified in requirements specification phase [S18]. Additionally, lead time could be decrease by increasing the collaboration with the market unit and the development unit [S18]. Similarly, there was a waste of waiting in design which could be improved by starting real work only when the purchase order is received, not when requests are received [S18].

Lead time, processing time and queue time metric were used to identify waste of waiting in testing phases [S18]. The improvement suggestion was to provide earlier beta version and making testing phases parallel. Many of the improvement ideas came from meetings where the value stream maps (VSM) were used as a base for discussion.

Cost types, rate of requirements over phases and variance in handovers were used to identify bottlenecks at Ericsson [S21]. They noticed that focusing on deadlines caused a lot of requirements to be transferred to system test phase close to the deadline. The improvement suggestion was to focus more on continuous delivery instead of focusing on market driven deadlines. Furthermore, Kanban was suggested as a development method to accomplish the continuous delivery capabilities.

Throughput and queue time metrics were used to identify bottleneck in network integration test phase which lead to using other testing practices in future projects [S26].

Rate of requirements over time was used to identify problems in the development process [S20]. One improvement suggestion was to change from push to pull-approach so that team can adjust the workload to enable continuous delivery. Another improvement suggestion was to add intermediate release versions so that integration and testing would happen more often and

problems could be identified earlier than close to the actual release. Similar solution was applied at Timberline inc. where requirements inventory was kept low which meant that design, implementation and testing could start earlier and problems in requirements would get caught sooner [S17].

Citrix online started measuring velocity for their Operations department as well [S8]. This led to other departments trying to decrease their products' Ops story points to enable faster releases. The reduction in story points was possible by creating hot deployment strategies and providing better documentation.

Mamdas, an Israel Air force IT department, were using burndown to follow their progress [28]. However, when they noticed that work remaining wasn't decreasing according to remaining resources they had to make changes. In their iteration summary meeting they decided to pursue senior engineers to help them create optimal development environments and continuous build systems. Also, they decided to evaluate customer requests in more detail to avoid over polishing features.

When story implementation flow metric showed a drop and project managers complained about clarifications about features from customer were late, a root cause analysis meeting was held [S13]. Also, after starting to use the implementation flow metric new policies were stated to keep the flow high: percentage of stories ready for sprint must be 100% and implementation flow must be at least 60%, and both of the metrics need to be reported montly. Root cause analysis was also conducted to decrease the amount of bounce backs at Timberline inc. [S17].

A team noticed their velocity estimations were inaccurate which led to dividing work items into smaller pieces to improve the accuracy of the estimates [P10].

The reasons for the values of metrics(burndown, check-ins per day, number of automated passing test steps, number of new and open defects) were discussed in iteration summary meeting because it can be hard to analyze metrics without understanding the context [S27]. Similarly, number of work items per phase was used to ask development unit about the values of the metric and the development unit confirmed that people felt overloaded as the metric suggested [S20]. Furthermore, if the values of number of work items were outside the control limits one could discuss with the developers about the workload [S22].

After analyzing long fix times for broken builds the team added automatic static code analysis checks to code check-in to catch defects earlier [S13]. Quality manager can change coding style guide and code standards based on the results of violations to static code analysis metric [S14].

4.4.2 Planning actions

Product owners use lead time to schedule high priority features and plan demo dates with customers [S23]. Using revenue per customer metric allowed higher valued features to be prioritized higher in the backlog. [S11]

Velocity / 2 metric was used as scoping tool for a release. The team had enough work not to sit idle, but there was still enough time to allow high priority bug fixes to be fixed [S23]. Effort estimates are used to scope the iteration and if there are tasks that cannot be completed before release date then they are excluded from the backlog [S12]. Velocity was used to define minimum delivery level for the iteration where 'must have' requirements are assigned, and a stretch goal where lower priority requirements are assigned [S2].

Expected date of completion was used so that other team members could plan their own work [S12].

4.4.3 Reactive actions

Metrics were used to cut down the scope or add more resources if it seemed not all tasks could be completed with current pace. When component level burndown was used to notice that a component was behind schedule, resources were added and scope was reduced for the release [S5]. Release burndown showed that work remaining was not decreasing fast enough so the scope of the release was decreased [S16]. If common compo time would show too much work, then tasks would be cut or more resources would be added [S17]. Similarly, if work balance is uneven, some roles have too much work while some don't have enough, people were trained in multiple roles, e.g customer support did testing and documentation engineers were taught how to input their material into the system. If team effectiveness is not high enough to complete tasks, resources from other teams can be used. Other actions that were suggested were reduction of tasks and working overtime [S3].

Metrics were also used to react to quality information. Monitoring cycle times revealed high time consumption on manual testing [S17]. The cause was an unmotivated person who was moved to writing automated test scripts which he liked more. Number of defects were used to delay a release when too many defects were noticed in a QA cycle [S10]. Quality manager interpreted results of static code analysis from the build tool and he would then make plans for necessary refactorings [S14]. When amount of written and passed unit tests was not increasing an alarm was raised, when the issue was discussed in a reflection meeting they understood that too much work

was put to a single tester writing the tests and once she was doing work for another project no tests were written [S28]. The team then started to learn to do them on their own as well, and later a dedicated tester was assigned to write the tests.

4.4.4 Motivate people

Metrics were used to motivate people to react faster to problems. Number of defects was shown in monitors in hallways and that motivated developers to fix defects [S3]. Total reported defects and test failure and success rate was also shown throughout the organization which motivated people to avoid problems and also fix problems fast [S3]. Fix time of failed build metric improved people's mindset to react to problems immediately [S13]. The metric was declared mandatory for all projects. Also, the reasons for long fix times were investigated. Build status was visible in minutes after commits, which helped to create a culture to react with high priority to broken builds [S4]. This helped to keep the main branch to be closer to deployable state at all times. Build status was used to motivate people to fix the build as fast as possible [S4]. Violations of static code analysis cause developers to immediately fix the issue because the violations can cause a broken build status [S14]. Additionally, developers get faster feedback on their work. Furthermore, developers have more confidence in performing major refactorings with the safety net the violations of static code analysis metric provides.

Metrics were used to change people's behavior. After meetings where technical debt categories were analyzed, team members agreed which categories they would focus in decreasing until the next meeting [S4]. Also, team members sought help from the architecture team for reducing technical debt, e.g by implementing automatic deployment or improving source code unit testability. Measuring the number of automated passing test steps changed teams behaviour to write more tests [S5]. Metrics were also used to prevent harmful behaviour such as cherry picking features that are most interesting to the team [S17]. Measuring work in progress (WIP) and setting WIP limits prevented cherry picking by enforcing only two features at a time and thus preventing them from working on lower priority but more interesting features. Defect trend indicator created crisis awareness and motivated the developers to take actions in hopes to avoid possible problems [S25].

There can also be negative effects in using metrics. Using velocity metric had negative effects such as cutting corners in implementing features to maintain velocity with the cost of quality [S6].

4.5 Important metrics in terms of statements

This section describes metrics that were considered important.

Progress as working code was considered as one of the cornerstones of agile [S30].

Story flow percentage and velocity of elaborating features were considered as key metrics for monitoring projects. Also, a minimum 60% value for flow was identified. Similarly, velocity for elaborating features should be as fast as velocity of implementing features. Also, they said using both metrics *"drive behaviors to let teams go twice as fast as they could before"*. [S13]

Net Promoter Score was said to be *"one of the purest measures of success"* [S7].

According to a survey, projects that were said to be definitely successful 77% measured customer satisfaction often or always. Also, the more often customer satisfaction would be measured the more likely it would be that the project would have good code quality and the project would succeed. [S1]

Story percent complete metric was considered valuable since it embraces test driven development - no progress is made before test is written. Also, percent complete metric is considered more accurate than previously used metric. Moreover, it gives normalized measure of progress compared to developer comments about progress. Additionally, story percent complete metric leverages existing unit testing framework and thus requires only minimal overhead to track progress. Team members seemed to be extremely happy about using the metric. [S29]

Pseudo-velocity was considered essential for release planning [S23].

In an agile survey [S1], project success had significant positive relationship with the following metrics: team velocity, business value delivered, running testing features, defect count after testing and number of test cases. However, there were no detailed descriptions of these metrics.

Effort estimates were consider important in release planning especially in terms of prioritization [S9].

Burndown was valuable in meeting sprint commitments [S7]. Similary, managers said burndown was important in making decisions and managing multiple teams [S5]. However, developers didn't consider burndown important [S5].

Top performing teams at Adobe estimated backlog items with relative effort estimates [S7].

Practitioners at Ericsson valued transparency and overview of progress that the metrics were able to provide to the complex product development with parallel activities, namely cost types, rate of requirements over phases

and variance in handovers [S21].

At another case at Ericsson Value Stream Maps (VSM) were used to visualize problem areas and possible improvements. Practitioners valued how the maps were easy to understand. Metrics that were used to build VSM were lead time, processing time and queue time. [S18]

Defects deferred was seen as a good predictor of post-release quality because it correlated with issues found by the customers [S7].

Defect prediction metrics predicted number of defects in backlog and defect trend indicator were seen important to decision making, and their use continued after the pilot period. Key attributes of the metrics were sufficient accuracy and ease of use. [S26]

Technical debt board that visualized the status of technical debt in categories was considered important because it gave a high level understanding of the problems and it was then used to plan actions to remove technical debt. It was proven to be useful in their context. [S4]

The following metrics were consider very useful in agile context: number of unit tests, test coverage, test-growth ratio and build status. The benefit for the number of unit tests is not well described except that it provides *"first insights"*. Test coverage provides info on how well the code is tested. Test-growth ratio is useful in projects where old codebase is used as basis for new features. Fixing broken builds prevents defects reaching customers. [S14]

4.5.1 Important metrics based on amount of evidence

Effort estimation metrics were used in many cases, so it could be perhaps said they are important since they provide scoping and prioritization.

Chapter 5

Discussion

5.1 Implications for practice

To provide implications to practice the findings are mapped to the principles of agile software development Beck et al. (2007) categorized by Patel & al. Patel et al. (2006). For each paragraph the naming by Patel et al. is used and references to the agile practices is provided by numbers.

Communication and Collaboration (principles 4 and 6) was reflected in metrics that motivated a team to act and improve, see **??**. Also, progress metrics were used to communicate the status of the project to the stakeholders, see **??**.

Team involvement (5,8) was reflected in metrics that motivated team to act and improve, see **??**. Also, to promote sustainable development metrics were targeted to balance the flow of work, see **??**.

Reflection (12) was visible in metrics that were used to identify problems and to change processes, see **??** and **??**.

Frequent delivery of working software (1,3,7) was directly identified in one paper, where the team measured progress by demonstrating the product to the customer [S30]. Additionally, there were cases where e.g. completed web-pages [S12] were the primary progress measure. Also, many metrics focused on progress tracking and timely completion of the iteration, see **??**. However, some other measures from **??** show that instead of working code agile teams followed completed tasks and velocity metrics.

An integral part of the concept of working software is measuring post-release quality, see **??**. This was measured by customer satisfaction, feedback, and customer defect reports. It was also common to use pre-release data to predict post-release quality. Agile developers tend to measure the end product quality with customer based metrics instead of the traditional quality

models, such as ISO/IEC 25010 (ISO/IEC, 2010).

Managing Changing Requirements (2) was seen in the metrics that support prioritization of features each iteration, see **??**. Additionally, different metrics helped keeping the internal quality of the product high throughout the development which then provided safe development of modifications from new ideas, see **??**.

Design (9,10,11) was seen in focus to measuring technical debt and using metrics to enforce writing tests before actual code, see **??**. Additionally, the status of build was continuously monitored, see **??**. However, the use of velocity metric had a negative effect on technical quality, see **??**. Many metrics focused on making sure that the right features were selected for implementation, see **??**, thus avoiding unnecessary work.

There were also metrics, or their usage, which were not agile in nature. E.g., maintaining velocity by cutting corners in quality instead of dropping features from that iteration [S6]. Also, adding people to project to reach a certain date [S5, S17] doesn't seem that agile compared to removing tasks. Adding people can have a negative impact to progress, considering the lack of knowledge and training time required. Moreover, the use of dates to plan interdependent tasks is not agile in nature [S12]. Instead, interdependencies should be visible in choosing the tasks to appropriate iterations. Also, the use of number of defects to delay a release [S10] is against agile thinking as one should rather decrease the scope to avoid such a situation.

Some agile metrics that work well for an agile team, such as tracking progress by automated tests [S28], or measuring the status of the build [S14] can turn against the agile principles if used as an external controlling mechanism. The fifth agile principle requires trust in the team, but if the metrics are enforced outside of the team, e.g., from upper management there is a risk that the metrics turn into control mechanisms and the benefits for the team itself suffer.

5.1.1 Comparison to prior studies

Only few papers have broadly studied the reasons for software metrics use in the context of agile software development. Hartmann and Dymond (2006) also highlight process improvement as one of the reasons for measurement in their agile metrics paper. Also, they emphasize that creation of value should be the primary measure of progress - which was also seen in this study.

Korhonen (2009) found in her study that traditional defect metrics could be reused in agile context - if modified. Defect metrics were also used in many of the primary studies.

Kitchenham's mapping study (Kitchenham, 2010) identified several code

metrics in academic literature. However, in this study almost no evidence of code metric use in the industrial agile context was found. Maybe agile practitioners consider code metrics self-evident and don't report them, or maybe code metrics aren't widely used by agile industrial teams.

5.2 Limitations

!FIXME **Add SLR vs survey - eli pöhkö tutkimusmenetelmä valittu tehtävään** FIXME! The large shares of specific application domains in the primary documents is a threat to external validity. Seven out of 29 studies were from enterprise information systems domain and especially strong was also the share of ten telecom industry studies out of which eight were from the same company, Ericsson. Also, Israeli Air Force was the case organization in three studies.

The threats to reliability in this research include mainly issues related to the reliability of primary study selection and data extraction. The main threat to reliability was having a single researcher performing the study selection and data extraction. It is possible that researcher bias could have had an effect on the results. This threat was mitigated by analysing the reliability of both study selection and data extraction as described in chapter 3.

Due to iterative nature of the coding process, it was challenging to make sure that all previously coded primary documents would get the same treatment, whenever new codes were discovered. In addition, the researcher's coding "sense" developed over time, so it is possible that data extraction accuracy improved during the analysis. In order to mitigate these risks a pilot study was conducted to improve the coding scheme, get familiar with the research method, refine the method and tools.

Some data from low scoring papers, e.g [S3], are not justified very detailed which could cause incorrect interpretations.

Chapter 6

Conclusions

This study presents the results from a systematic literature review from 29 !Fixme **numero** Fixme!primary studies. According to the researcher's knowledge there is no previous systematic reviews of measurement use in the context of industrial agile software development. This study classifies and describes the main measurement types and areas that are reported in empirical studies. This study provides descriptions of how and why metrics are used to support agile software development.!Fixme **lisää important metrics ja metrics categories** Fixme! This study also analyzed how the presented metrics support the twelve principles of Agile Manifesto (Beck et al., 2007).

The results indicate that the reasons and use of metrics is focused on the following areas: **??**, **??**, **??**, **??**, **??**, **??** and **??**.

This paper provides researchers and practitioners with an useful overview of the measurements use in agile context and documented reasonings behind the proposed metrics. This study can be used as a source of relevant sources regarding researchers' interests and contexts.

Finally, this study identified few propositions for future research on measuring in agile software development. First, in the academia lot of emphasis has been given to code metrics yet this study found little evidence of their use in agile context. Second, the applicable quality metrics for agile development and the relationship of pre-release quality metrics and post-release quality are important directions of future research. Third, this study found that planning and tracking metrics for iteration were often used indicating a need to focus future research efforts on these areas. Fourth, use of metrics for motivating and enforcing process improvements can be an interesting future research topic.

!Fixme **Add future work - negative effects of metrics. negative motivation effects of metrics.** Fixme!

!Fixme **lisää important metrics ja metric categories** Fixme!

It found 220 hits 7 November 2013.

The third search string was:

TITLE-ABS-KEY(software AND (agile OR lean OR "crystal method" OR "crystal clear" OR dsdm OR "dynamic systems development method" OR fdd OR "feature driven development" OR "agile unified process" OR "agile modeling" OR scrumban OR kanban OR scrum OR "extreme programming" OR xp) AND (measur* OR metric OR diagnosticOR monitor*)) AND (LIMIT-TO(LANGUAGE, "English")) AND (LIMIT-TO(SUBJAREA, "BUSI")) AND (EXCLUDE (SUBJAREA, "ENGI") OR EXCLUDE(SUBJAREA, "COMP"))

It found 42 hits 10 December 2013.

Appendix B

Inclusion and exclusion criteria

Inclusion criteria

- Papers that present the use and experiences of metrics in an agile industry setting.

Exclusion criteria

- Papers that don't contain empirical data from industry cases.
- Papers that are not in English.
- Papers that don't have agile context. There is evidence of clearly non-agile practices or there is no agile method named. For example, paper mentions agile but case company has only three releases per year.
- Paper is only about one agile practice, which is not related to measuring.
- Papers that don't seem to have any data about metric usage. Similarly, if there are only a few descriptions of metrics but no other info regarding reasons or usage.
- Papers that have serious issues with grammar or vocabulary and therefore it takes considerable effort to understand sentences.
- Papers where the setting is not clear or results cannot be separated by setting, for example surveys where there is data both from academia and industry.
- Papers where the measurements are only used for the research. For example author measures which agile practices correlate with success.

Appendix C

Quality assesment questions

1. Is this a research paper?
2. Is there are a clear statement of the aims of the research?
3. Is there an adequate description of the context in which the research was carried out?
4. Was the research design appropriate to address the aims of the research?
5. Was the recruitment strategy appropriate to the aims of the research?
6. Was there a control group with which to compare treatments?
7. Was the data collected in a way that addressed the research issue?
8. Was the data analysis sufficiently rigorous?
9. Has the relationship between researcher and participants been considered adequately?
10. Is there a clear statement of findings?
11. Is the study of value for research or practice?

Appendix D

Metric distribution by primary studies

Metrics by primary studies

ID	Metrics
[S1]	Business value delivered, customer satisfaction, defect count after testing, number of test cases, running tested features
[S2]	Velocity
[S3]	Critical defects sent by customer, open defects, test failure rate, test success rate, remaining task effort, team effectiveness
[S4]	Technical debt in categories, build status, technical debt in effort
[S5]	Burndown, check-ins per day, number of automated passing test steps, faults per iteration
[S6]	Velocity, story estimates
[S7]	Burndown, story points, # of open defects, defects found in system test, defects deferred, Net Promoter Score
[S8]	Story points, task effort, velocity, operation's velocity
[S9]	Effort estimate, actual effort
[S10]	# of defects/velocity
[S11]	Revenue per customer
[S12]	Task's expected end date, effort estimate, completed web pages, task done
[S13]	Fix time of failed build, story flow percentage, percentage of stories prepared for sprint, velocity of elaborating features, velocity of implementing features

[S14]	Build status, test coverage, test growth ratio, violations of static code analysis, # of unit tests
[S15]	Effort estimate / effort estimate / effort estimate / effort estimate
[S16]	Sprint burndown, release burndown, cost performance index, schedule performance index, planned velocity
[S17]	Common tempo time, number of bounce backs, cycle time, work in progress, customer satisfaction(Kano analysis), effort estimate kits
[S18]	Lead time, processing time, queue time
[S19]	Change requests per requirement, fault slips, implemented vs wasted requirements, maintenance effort, lead time
[S20]	Number of requests from customers, number of work items per phase
[S21]	Rate of requirements per phase, variance in handovers, requirement's cost types
[S22]	# of requirements per phase, lead time
[S23]	Work in progress, average velocity, cycle time, pseudo velocity
[S24]	Lead time, work in progress
[S25]	Defect trend indicator, # of defects in backlog, predicted # of defects
[S26]	Throughput, queue
[S27]	Burndown, check-ins per day, number of automated passing test steps, number of new and open defects
[S28]	Burndown, number of automated passing test steps, check-ins per day
[S29]	Story estimate, story complete percentage
[S30]	Progress as working code
[S31]	Costs, schedule
